Natl. Acad. Sci. USA, Vol. 74, p. 560-564 (1977). In this method an oligonucleotide primer is attached to a solid support and a second, second complementary oligonucleotide is annealed to the portion of the primer attached to the solid support. The sequence of the first oligonucleotide is then determined. The second complementary oligonucleotide is then removed from the solid support and the sequence of the second oligonucleotide is determined. This process is repeated until the entire sequence is determined. Although this method has been used successfully, it has several deficiencies. For example, since the sequence of the oligonucleotide primer is determined by the base sequence of the oligonucleotide that it anneals to, the base sequence of the oligonucleotide that anneals to the oligonucleotide primer is not known. Thus, once this method is applied, the sequence of the oligonucleotide attached to the solid support cannot be determined without first knowing the sequence of the oligonucleotide that attached to it. The necessity of first determining the sequence of the oligonucleotide that attaches to the oligonucleotide primer has limited the applicability of this method to situations where the sequence of the oligonucleotide that attaches to the primer is known and is not otherwise affected by its attachment to the primer. Methods have also been developed to sequence oligonucleotides without attaching the oligonucleotide to a solid support. In U.S. Pat. No. 4,869,202 a plurality of oligonucleotides are synthesized and then combined on a surface, such as a microscopic glass slide. A polyfunctional compound containing a reactive group is then reacted with a surface bound oligonucleotide and is then split to give a fluorescent compound. The fluorescent compound is then analyzed to determine the sequence of the oligonucleotide. Although such methods are useful, the difficulty in synthesizing a large
